

Western Electric 336A and 349A Vacuum Tubes

Classification—Suppressor-grid pentodes with indirectly heated cathodes, intended for Class A Service

The 336A and 349A tubes differ in heater ratings and type of base. In all other respects they are identical.

These tubes are intended for use primarily as audio-frequency power amplifiers where power outputs of approximately 3.5 watts are required with a plate voltage not in excess of 250 volts. The suppressor grid is permanently connected to the cathode within the tube.

Dimensions and Connections—The outline diagrams of the tube and base giving the dimensions and the arrangement of electrode connections to the base terminals for the 336A tube are shown in Figure 1. Similar information for the 349A tube is shown in Figure 2.

Base and Mounting—The 336A tube employs a small six-pin thrust type base with silver-plated pins. It is adapted for use in a standard six-contact type socket, preferably one provided with silver-plated contacts such as the Western Electric 144B socket.

The 349A tube employs a small shell octal seven-pin base.

These tubes may be mounted in any position.

Average Direct Interelectrode Capacitances

Control grid to plate	0.65 $\mu\mu f$
Control grid to heater, cathode and screen grid	12 $\mu\mu f$
Plate to heater, cathode and screen grid	9 $\mu\mu f$

Heater Ratings

	<u>336A Tube</u>	<u>349A Tube</u>
Heater voltage.....	10.0	6.3 volts, a-c or d-c
Nominal heater current.....	0.64	1.0 ampere

The heater elements of these tubes are designed to operate on a voltage basis and should be operated at as near the rated voltage as practicable.

The voltage between the cathode and heater should not exceed 60 volts.

Characteristics—Figures 3 and 4 show plate current and screen-grid current respectively, as functions of control-grid voltage for several values of screen-grid and plate voltage. In all curves the plate voltage is equal to the screen-grid voltage. Plate current and screen-grid current are shown as functions of plate voltage in Figures 5 and 6, respectively, for a screen-grid voltage of 250 volts and for several values of control-grid voltage. Transconductance and plate resistance as functions of control-grid voltage are shown in Figure 7 for two values of screen-grid and plate voltage. The plate voltage in each case is equal to the screen-grid voltage. Transconductance and plate resistance as functions of screen-grid voltage are shown in Figure 8 for a plate voltage of 250 volts and two values of control-grid voltage.

Limiting Conditions For Safe Operation

Maximum plate voltage.....	250 volts
Maximum screen-grid voltage.....	250 volts
Maximum cathode current (Plate current plus screen-grid current)....	50 milliamperes
Maximum direct screen-grid current.....	10 milliamperes

For fixed bias, the resistance in the grid circuit should not exceed 50,000 ohms. The maximum grid resistance, when self-bias is used, may be 0.5 megohm.

Operating Conditions and Output—Table No. 1 shows amplification factor, plate resistance, transconductance and performance data for a number of typical operating conditions with the tubes operating singly as pentodes. Less severe operating conditions should be selected in preference to maximum operating conditions wherever possible. The life of the tube at maximum conditions will be shorter than at less severe conditions.

The performance data include the fundamental power output for the indicated values of load resistance and input voltage, and the maximum second and third harmonic levels for input voltages not exceeding the indicated values. Under certain conditions the maximum second harmonic level occurs at a lower input voltage than that given in Table 1. The power output is given in watts and the harmonic levels in decibels below the fundamental.
